Job Market Paper

Do Urban Parks Promote Racial Diversity?
Evidence from New York City 2020

Abstract: While some prominent scholars and policymakers have argued that public space promotes racial diversity, empirically it remains unclear whether these places play a role in creating diverse social environments for the city's residents. Focusing on parks in New York City as the exemplar of modern public space, I estimate the causal relationship between access to parks and individually experienced diversity. To do so, I introduce a measure of racial diversity that captures one's level of exposure to diverse others in places visited on a daily basis, utilizing a novel dataset featuring individual GPS tracking data for more than 60 thousand Twitter users in the New York metro area. My empirical strategy relies on obtaining a time-varying measure of access to parks that incorporates information about ongoing construction and repair works across the city. The results show that additional 10 acres of parkland within the 5 km radius from home increase individual chances of encounters with other racial/ethnic groups by 1 p.p. The effect is sizable: for reference, transitioning from the current state to the random mixing scenario would require a 9 p.p increase in diversity for an average Black or African American individual and a 3.5 p.p increase for an average White. I also provide evidence to suggest that park accessibility affects the diversity of White and Black residents differently: for parks located closer to home, the effect appears to be more pronounced for Whites than Blacks, indicating that parks in the majority-white neighborhoods are able to attract a broader range of visitors compared to the local parks in majority-black neighborhoods.

Other Working Papers

Do Local Businesses Benefit from Stadiums? (with *Dmitry Sedov*)
The Case of Major Professional Sports Leagues Arenas 2020

Abstract: Stadiums cost hundreds of millions of dollars to build and are often subsidized by public sources. In many cases, subsidies are allocated on the premise that sports events benefit the local economy by bringing new customers to nearby businesses. We use daily foot traffic records covering major sports league facilities and their surrounding commercial establishments to pin down the size and spatial distribution of such spillovers. By employing fixed effects and IV estimation strategies, we show that benefits are heterogeneous across sports and business sectors. We find that baseball and football stadiums generate substantial traffic to businesses in the food & accommodation and retail trade categories. However, the corresponding spillover effects of basketball and hockey stadiums are not significant across the studied business sectors. Moreover, using the data on subsidies allocated to the facilities in our sample, we show that only the top quartile of the most attended baseball stadiums generate enough spillover benefits to offset the public funds they receive.

Work and Teaching Experience

Research Assistant

For Prof. Christian Moser, Columbia University 2017-2018

My task was to perform data cleaning and geocoding for about 8 million raw address lines using Python and ArcGIS API. I was also responsible for providing summary reports and creating custom maps to visualize the data.

JOB MARKET PAPER

The Effects of Exposure to Electoral Propaganda: Evidence from Spain (2020)

Abstract: I measure the effects of street-level political advertising on voting behavior. I use a novel dataset on ad location in a major Spanish city during elections for the national parliament as well as granular socio-economic and voting data. This set-up, where more than two parties are running for office and elections are very competitive, allows me to explore the heterogeneous effects of ads across parties as well as how parties' ads affect other parties' vote shares. To identify the effects of parties' ads, I exploit legally mandated randomized assignment of ad location to parties across multiple years. I find that a party's own ads have a positive effect on a party's vote share, although the effects are quite heterogeneous across parties. A one standard deviation increase in the number of ads increases a party's vote share by 0.79 percentage points on average. Ads of parties that have a platform that is ideologically distant have a negative effect on a party's vote share. Instead, ads of parties that are close competitors may act either as complements or substitutes in different years.

RESEARCH PAPERS AND PRESENTATIONS

OTHER WORKING PAPERS

The Effect of Incentives on Choices and Beliefs in Games. An Experiment (2020)

with Duarte Gonçalves

Abstract: Do incentive levels matter in strategic environments? Existing models disagree not only on whether gameplay is affected by incentive levels, the overall stakes players face, but also on why. In this paper, we present experimental evidence establishing that the level of incentives affects both gameplay and beliefs. Holding fixed the actions of the other player, we find that, in the context of dominance-solvable games, higher incentives make subjects more likely to best-respond to their beliefs. Moreover, higher incentives result in more responsive beliefs but not necessarily less biased. We provide evidence that incentives affect effort and that it is effort, and not incentives directly, that accounts for the changes in belief formation. The results support models where, in addition to choice mistakes, players exhibit costly attention.

The Effects of Economic Shocks on New Party Emergence and Changes in Voting Patterns (2020)

Abstract: This paper analyses the effects of an economic shock on the emergence of new parties and other changes in voting parties by using regional variation in the exposure to the shock. I find that a worsening of economic conditions as measured by unemployment rate leads to an increase in electoral competition and volatility. In particular, the deeper the effects of the recession in a area, the larger the number of new parties emerge and become more successful and there is an increase in the changes in vote shares. On the other hand, the vote share of parties previously in government decreases and a decrease in vote share concentration.

Job Market Paper: The role of confidence over timing of investment information

Abstract: I present an investment environment wherein investors demand an asset based on perfectly informative signals, but face uncertainty about the timing of their information acquisition. I show that this reduces the demand and price for every period but that in the limit price as number of periods increases price converges to the true value of the asset. By introducing a concept of confidence over the time in which they receive a signal, I show that the impact of uncertainty can be exaggerated in either a negative or positive direction, with the limit price reflecting the true value of the asset depending on the type of confidence under consideration.

Working Papers:

Stackelberg oligopoly with positional uncertainty

Abstract: In a Stackelberg oligopoly setting, two firms set quantity without knowing whether they are the first or second in the market. I find that with a common prior, positional uncertainty always leads to a more competitive level of quantity. This finding is exacerbated when firms do not share a common prior and the sum of their prior beliefs of moving first exceeds unity. Even in the presence of a common prior and many identical firms as the number of firms increases, the equilibrium quantity in the presence of positional uncertainty can exceed that of perfect competition.

Social learning with limited histories

Abstract: I adapt the standard observational learning environment and introduce a limited history of observation. When agents can only observe the action of the previous agent, complete learning still occurs but with a loss of welfare. When a limited history is coupled with uncertainty over position in the queue of actors, welfare further drops - increasing in uncertainty - but complete learning still occurs in the limit. These results are illustrated with a canonical linear model but learning holds in a more general setting satisfying the usual social learning assumptions.

Job Market Paper

“Treatment Effects in Bunching Designs: The Impact of the Federal Overtime Rule on Hours”

The Fair Labor Standards Act (FLSA) mandates overtime premium pay for most U.S. workers, but a lack of variation in the rule has made it difficult to assess its impact on hours worked. I use bunching observed at 40 hours in a new administrative dataset of weekly paychecks to estimate this effect. To do so, I develop a framework in which bunching at a choice-set kink is informative about causal effects in a way that is robust across underlying structural models, generalizing previous approaches. Under a non-parametric shape constraint on the distribution of hours and flexible assumptions on choice, a local average treatment effect among bunchers is partially identified. The bounds are informative in the overtime context and suggest that covered hourly workers in the U.S. work an average of at least half an hour less as a result of the FLSA mandate, in weeks that they do work at least 40 hours. This delivers an estimate of the wage elasticity of hours demand of -0.04 .

Working Papers

“A Vector Monotonicity Assumption for Multiple Instruments” (September 2020)

When a researcher wishes to use multiple instrumental variables for a single binary treatment, the familiar LATE monotonicity assumption can become restrictive: it requires that all units share a common direction of response even when different instruments are shifted in opposing directions. What I call *vector monotonicity*, by contrast, simply restricts treatment status to be monotonic in each instrument separately. This is a natural assumption in many contexts, capturing the intuitive notion of “no defiers” for each instrument. I show that in a setting with a binary treatment and multiple discrete instruments, a class of causal parameters is point identified under vector monotonicity, including the average treatment effect among units that are responsive to any particular subset of the instruments. I propose a simple

“2SLS-like” estimator for the family of identified treatment effect parameters. An empirical application revisits the labor market returns to college education.

JOB MARKET PAPER

[Sequential Sampling and Equilibrium](#) (2020)

Abstract: I propose an equilibrium solution concept in which players sequentially sample to resolve strategic uncertainty over their opponents' distribution of actions. Bayesian players sample from their opponents' distribution of actions at a cost and make optimal choices given their posterior beliefs. The solution concept makes predictions on the joint distribution of players' choices, beliefs, and decision times, and generates stochastic choice through the randomness inherent to sampling, without relying on indifference or choice mistakes. It rationalizes well-known deviations from Nash equilibrium such as the own-payoff effect and I show its novel predictions relating choices, beliefs, and decision times are supported by existing data.

Job Market Paper

“Emerging Market Business Cycles with Heterogeneous Agents”

A central question in open economy macroeconomics is how to explain excess consumption volatility in emerging economies. This paper argues that to understand this phenomenon, it is important to take into account households' idiosyncratic income risk, precautionary saving, and marginal propensities to consume (MPCs). The paper makes a first attempt to study emerging market business cycles in a heterogeneous-agent open economy model. Financial frictions determining asset liquidity in the model are calibrated such that MPCs are as high as empirical estimates from emerging market micro data, which are substantially greater than the U.S. MPC estimates. I then estimate the model using macro data and Bayesian methods. The model captures the observed excess consumption volatility well. To highlight the importance of high-MPC households in driving this result, I show that excess consumption volatility disappears when households are counterfactually replaced with those exhibiting U.S. MPCs. High-MPC households contribute to consumption volatility through i) their strong consumption response to resource fluctuations and ii) large consumption reduction when assets become more illiquid. The transmission mechanisms of trend shocks and interest rate variations that previous studies use to explain excess consumption volatility are dampened because households significantly deviate from the permanent income hypothesis, on which these mechanisms crucially depend.

Working Papers

“MPCs and Liquidity Constraints in Emerging Economies”

For the first time in the literature, this paper estimates the marginal propensity to consume (MPC) out of transitory income shocks using micro data for an emerging economy. To this end, I employ a nationally representative Peruvian household survey. Two striking differences emerge when the Peruvian MPC estimates are compared with U.S. MPC estimates obtained by the same method. First, the mean MPC of Peruvian income deciles (0.632) is much higher than that of U.S. deciles (0.089). Second, within-country MPC heterogeneity over the deciles is substantially stronger in Peru. Patterns in the consumption growth of the deciles and the MPCs of unconstrained top income groups delineated by an MPC homogeneity test suggest that liquidity constraints are important for explaining both the higher mean MPC and the stronger MPC heterogeneity in Peru.

“Who Bears Aggregate Fluctuations in Emerging Economies?”

This paper assesses how rich and non-rich households share aggregate consumption and income fluctuations differently between a developed economy and an emerging economy. To this end, I apply the fluctuation decomposition method devised by Parker and Vissing-Jorgensen (2009) to the U.S. and Peruvian household surveys. The U.S. bottom 80% consumption group contributes to aggregate consumption fluctuations 0.8 times as much as it does to aggregate income fluctuations, while the Peruvian bottom 80% consumption group contributes to aggregate consumption fluctuations 1.7 times as much as it does to aggregate income fluctuations. This result suggests that non-rich households in emerging economies could be important contributors to the phenomenon of excess consumption volatility in emerging economies. The existing theories for this phenomenon do not square well with the empirical finding of this paper because these theories involve mechanisms that non-rich households in emerging economies are less able to accommodate.

Pre-doctoral Publication

(In Korean) **“The Value-Added and the Productivity of Korean Banking Industry,”** with Se-Jik Kim, *Economic Analysis* 21(3), 2015, 35-74.

This paper aims to evaluate the core ability of Korean banks to distinguish more productive firms from less productive ones and provide loans selectively to the former. To this end, we calculate the value-added of Korean banks from the distribution side, and then assess total factor productivity (TFP) of the banks using the financial statement data for the period 1991-2013. We find that the productivity of the Korean banking sector has not far grown from the level of the early 1990s. The banking sector productivity, which plummeted during the 1997 Korean financial crisis, rebounded in the mid-2000s but retreated again to its level of 1991 in recent years. We also discover that major declines in the Korean banking sector productivity can be largely attributed to tremendous losses from huge bad loans. These findings suggest that Korean banks may not have fully developed their capacity to select high-productivity firms and reduce bad loans for the last two decades.

JOB MARKET PAPER **"Access to Care in Equilibrium"**

Abstract: This paper studies consumer access to medical care as an equilibrium outcome of a market without prices. I use data from the Northern Ontario primary care market to estimate an empirical matching model where patients match with physicians. The market is cleared by a non-price mechanism: the effort it takes to find a physician. I use the model to study the distribution and determinants of access to care and to evaluate the effectiveness of policy remedies. I find that access to care is low and unevenly distributed. 26% of patients who would see a physician in a full access environment do not receive care in 2014. The issue is particularly acute in rural areas. Further, physicians discriminate in favor of patients with higher expected utilization, thereby increasing access for older and sicker patients while decreasing access for younger and healthier patients. The estimated model is used to evaluate two policies: grants to incentivize physicians to practice in low-access areas and a payment reform that provided incentives for physicians to increase the numbers of patients on their books. While both policies are partially successful, the model suggests potential improvements.

OTHER WORK IN PROGRESS **"Market Segmentation and Competition in Health Insurance"**
(with Kate Ho and Michael Dickstein)

Shortened Abstract: We study the welfare consequences of market segmentation in private health insurance in the US, where households obtain coverage either through an employer or via an individual marketplace. Using a model of insurance demand and insurer pricing, we demonstrate that recent policies to combine the two markets may generate both benefits and costs to society. We employ data from Oregon's small group and individual markets to estimate household preferences and predict premiums and costs under a counterfactual pooled market. We use the estimated model to simulate the welfare consequences of pooling markets, accounting for plan premium setting, household participation and the allocation of households across coverage levels.

"Access to Care or Money Down the Drain? Evaluating the National Health Service Corps' Effects on Staffing Outcomes of Health Clinics"
(with Iain Bamford)

Shortened Abstract: The National Health Service Corps provides school loan repayments and scholarships to incentivize health practitioners to practice in underserved areas. To participate in the program, health practitioners must practice in eligible locations or clinics. This paper exploits quasi-exogenous variation in clinic eligibility to estimate the effect of the program on health clinic outcomes.

ONGOING RESEARCH

- Risk Premia, Informality, and the Business Cycle

Job Market Paper. Joint with Livio Maya.

The share of informal jobs increases in downturns and decreases in booms. We provide a novel channel to explain this stylized fact. The key insight is that the breakdown of the workforce into formal and informal jobs over the business cycle behaves like the weights of an aggregate portfolio. Hiring a worker formally has advantages in terms of productivity, but is inherently risky due to severance payment requirements that prevent the termination of labor contracts that become unprofitable during recessions. The fact that the share of informal jobs increases in downturns reflects portfolio rebalancing towards the less risky asset: informal labor. We embed the risk structures of formal and informal jobs in a search and matching model with aggregate uncertainty, which we calibrate with data from Brazil. We find that a *countercyclical price of risk* is an essential ingredient for producing predictions about the cyclicity of labor market variables in line with the data. We simulate a reduction in severance payments in economies with different degrees of time variation in the price of risk (TVPR). We find substantial differences in the sensitivity of formalization to the reduction in the severance requirements across specifications. Moreover, reducing severance payments reduces unemployment volatility when the TVPR degree is low, and increases for sufficiently high TVPR. The results show that correctly specifying TVPR is consequential for policy analysis.

- The Repression of Informal Labor: Aggregate Effects and Transition Dynamics

Joint with Livio Maya.

This paper studies the effects of public policies designed to fight informal labor activity. We propose a general equilibrium model with heterogeneous agents in which the income process follows from a search model. We calibrate it to generate stylized income/informality facts from Brazilian household-level data. Firms opt between offering formal or informal contracts and have heterogeneous ability to operate informally. Such heterogeneity leads some productive firms to choose informal contracts. It allows the model to produce similar income averages among high-income workers in the formal and informal sector, a property we find in the data. We then use the model to simulate the economy's response to the repression of informal labor activity by the government. Our simulation suggests that short and long-run impacts differ. General equilibrium effects matter for both. In the long run, households' welfare and average firm productivity improve, and unemployment decreases. However, in the short run, reduced aggregate savings leads to a 4% increase in interest rates and a 2.5% increase in the unemployment rate. We also show that if the government fails to transfer back to households the additional tax revenue, these effects hold in the long run as well. In addition, if the policy is anticipated by economic agents, then output declines and informality increases prior to implementation. In all cases, households with greater wealth experience larger welfare gains.

RESEARCH PAPERS

Who Writes the Check to the Government Does Matter: Evidence from Firm-to-Firm Links (Job Market Paper)

The design of tax collection is largely considered to be inconsequential in the academic literature, yet policy makers frequently implement reforms to it. Combining a new administrative dataset on firm-to-firm links from Italy and a quasi-experimental research design, I study how firms and markets adapt to a reform of the collection of Value Added Tax (VAT). The reform shifted the responsibility to remit payments of VAT from sellers to “trusted” buyers, such as government entities and large firms. I present three main findings. First, firm-to-firm links subject to the new rules are more likely to become inactive after the introduction of the new rules. Second, I find that the reform was costly for the average firm. Firms more exposed to the reform experienced lower sales and higher exit rates, relative to the counterfactual. Third, I document that the burden of the reform is not evenly distributed across firms. Small firms are hit hardest, while large firms do not appear to be negatively affected. As a result, I show that markets more exposed to the reform became more concentrated.

Importing Inequality: Migration, Mobility, and the Top 1 percent (joint with Arun Advani, Felix Koenig, and Andy Summers)

In this paper we study the contribution of migrants to the rise in UK top incomes. Using administrative data on the universe of UK taxpayers we show migrants are concentrated at the top of the income distribution, with migrants twice as prevalent in the top 0.1 percent as anywhere in the bottom 96 percent. These high incomes are predominantly from labour, rather than capital, and migrants are concentrated in only a handful of industries, predominantly finance. Almost all (85%) of the growth in the UK top 1% income share over the past 20 years can be attributed to migration.

Job Market Paper

[Competing Persuaders in Zero-Sum Games](#) (with Zhihan Cui, 2020)

Abstract: We study a Bayesian Persuasion game with multiple senders employing conditionally independent experiments. Senders have zero-sum preferences over what information is revealed. We characterize when a set of states cannot be pooled in any equilibrium, and in particular, when the state is (fully) revealed in every equilibrium. The state must be fully revealed in every equilibrium if and only if sender utility functions are sufficiently nonlinear. In the binary-state case, the state is fully revealed in every equilibrium if and only if some sender has nontrivial preferences. Our takeaway is that 'most' zero-sum sender preferences result in full revelation.

JOB MARKET PAPER

Transport Infrastructure Improvements and Spatial Sorting: Evidence from Buenos Aires

How do improvements in the urban transport infrastructure affect the spatial sorting of residents with different levels of income and education within a city? What are the welfare effects of improving urban transit once we take into account these patterns of spatial sorting? In this paper, I study the effects of the construction of a bus rapid transit system (BRT) on the spatial reorganization of residents within the city of Buenos Aires, Argentina. To do so, I leverage an individual level panel data set of more than two million residents with which I can describe intra-city migration patterns. I first find reduced form evidence that the construction of the BRT increased the spatial segregation between high and low-skilled residents within the city. I then develop a dynamic quantitative spatial equilibrium model of a city with heterogeneous workers that allows me to quantify the welfare effects of this BRT system while taking into account these spatial sorting patterns. With this quantitative framework, I can measure the average welfare gains for residents that were living near the BRT lines before these were built. I find that welfare gains were very similar between high- and low-skilled workers living in the same locations, but very different within skill levels across locations. Residents living near a BRT line in neighborhoods with the lowest share of high-skilled residents saw welfare gains close to 1% on average, while residents living near a BRT line in neighborhoods with the highest high-skilled share saw welfare gains around 0.5% on average.

EDUCATION

Ph.D.	Department of Economics, Columbia University	2015 – Expected 2021
B.S.	Hong Kong University of Science and Technology Major: Mathematics and Economics, Department of Mathematics Minor: Information Technology, Department of Computer Science and Engineering	2011 – 2015
Exchange Student	Department of Economics, Northwestern University	2014

RESEARCH INTEREST

Entrepreneurial Finance, Field Experiment, Empirical Corporate Finance, Applied Microeconomics

JOB MARKET PAPER

“Discrimination in the Venture Capital Industry: Evidence from Two Randomized Controlled Trials”, 2020

Abstract: This paper examines the presence of discrimination in early-stage investors using two randomized controlled trials with real venture capitalists mainly from the U.S. The first experiment invites real U.S. investors to evaluate multiple randomly generated startup profiles, which they know to be hypothetical, in order to be matched with high-quality startups from collaborative incubators. Investors can also donate money to randomly displayed startup teams to show their anonymous support during the COVID-19 pandemic. The second experiment utilizes a new email technology which tracks detailed information acquisition behaviors of global VC investors in response to hypothetical pitch emails with randomized startups' information. I find three main results: (i) Investors are biased towards female, Asian and older founders in lower-stake situations while biased against female, Asian and older founders in higher-stake situations; (ii) The source of bias comes from implicit bias, statistical discrimination, taste-based mechanisms, and attention discrimination; and (iii) I detect a temporary, stronger bias against Asian founders during the COVID-19 outbreak, which started to fade after April 2020. I also develop a consistent decision-based heterogeneous effect estimator by using within-individual level randomization.

WORKING PAPER

“How Venture Capitalists Bet: Evidence from Two Randomized Controlled Trials”, 2020

Abstract: Understanding the importance of both human and non-human assets in firms' early-stage financing process is crucial to examining theories of the firm. However, it is difficult to empirically generate causal evidence due to data limitations and the lack of exogenous variations. This paper uses two randomized controlled trials with real venture capitalists mainly from the U.S.

to identify characteristics of both the project and their teams that causally affect venture capitalist funding. Specifically, I also check their relative importance on investors' decisions. I find that multiple team characteristics (i.e. founder's educational background and previous entrepreneurial experiences) and project characteristics (i.e. traction, business model, location, comparative advantages, etc.) causally affect investors' contact and investment interests by influencing their evaluation of startups' potential financial returns, risk, and loyalty. Although project traction matters the most in my experimental setting, it is fundamentally the investors' belief in the startup's profitability that matters the most. I also find the traditional correspondence test method, to an extent, inappropriate in testing the significance of project characteristics in virtue of the different "signal-to-noise ratio" problem..

"ESG and Venture Capital Investment: Experimental Evidence", 2020

Abstract: This paper examines the effect of ESG characteristics of startups on venture capitalists' investment interest by employing a randomized controlled method. I invite real U.S. investors to evaluate multiple randomly generated startup profiles, which they know to be hypothetical, in order to be matched with high-quality startups from the collaborative incubators. I find the following three main results: (i) Aiming for environmental and social impact causally lowers investors' expectation of the startup's future profitability rather than risk. Therefore, profit-driven investors are less likely to contact or invest in ESG-related startups. (ii) Profit-driven investors have a stronger implicit belief that ESG related startups would not seek for collaboration with them. (iii) There is a positive interaction effect between ESG characteristics and the founder's educational background, indicating that a high level of education helps improve investor's expectation of the ESG startup's profitability. Experimental results challenge the traditional thesis of "doing well by doing good" and support the recent findings that investors derive non-pecuniary utility from impact investing while sacrificing their financial returns.

"The Microstructure of U.S. Housing Market: Evidence from Millions of Bargaining Interactions", 2020 *with* [Haaris Mateen](#), [Franklin Qian](#)

Abstract: We study patterns of behavior in the U.S. housing market bilateral bargaining situations using a rich new data set describing bid-level housing transaction behaviors occurring in over 150,000 listings from a housing brokerage platform. We compare observed behavior to predictions from the large theoretical housing literature. Model testing outcomes show that existing housing micro-structure models do not adequately explain the under-reaction behaviors in sellers' estimates of the final sales price of the house. We also provide novel micro-level evidence describing how home buyers' characteristics affect their bargaining power and surplus allocation in these bilateral bargaining process in the housing market. These observations suggest that housing transaction behaviors, which are neither incorporated nor explained by existing theories, play an important role in the U.S. housing market.
